

OPTICROP: SMART AGRICULTURAL PRODUCTION OPTIMIZATION ENGINE

BRAINSTORMING & IDEA PRIORITIZATION

1. Project Idea Exploration

Several project ideas were explored aimed at optimizing agricultural outcomes through technological intervention. The brainstormed concepts focused on leveraging raw soil and environmental parameters to construct a production advice matrix. Four key ideas were analyzed for feasibility, impact value, data availability, and implementation complexity:

- Crop Recommendation Classifier: Predict optimal crops based on nitrogen, phosphorous, potassium, temperature, humidity, pH, and rainfall.
- Expected Yield Predictor: Implement a regressor incorporating geographic region, planting season, and chemical soil composition to forecast crop yield.
- K-Means Soil Health Clustering: Group soil chemistries into clusters to diagnose soil structural profiles automatically.
- Leaf Disease Recognition: Build an image classification network to diagnose crop diseases.

2. Priority Evaluation Matrix

Feature Concept	Feasibility	Impact Value	Data Availability	Final Priority
Crop Recommendation Classifier	High	Critical	Excellent	P1 (Core Product)
Crop Yield Forecaster	High	Critical	Good	P1 (Core Product)
K-Means Soil Clustering	High	High	Excellent	P2 (Core Features)
Leaf Disease Classifier	Medium	High	Low (Mock)	P3 (Future Scope)

3. Selection Decisions & Rationale

The Crop Recommendation Classifier and Expected Yield Forecaster were selected as P1 deliverables because they resolve the primary pain points of farmers (crop-soil mismatches and financial output uncertainty). K-Means clustering was chosen as a diagnostics tool to group soil properties. Leaf Disease classification was deferred to a future development phase due to the lack of high-fidelity leaf image training datasets in the project timeline.
