

OPTICROP: SMART AGRICULTURAL PRODUCTION OPTIMIZATION ENGINE

PROBLEM STATEMENT DEFINITION

1. The Crisis in Traditional Farming

Modern agricultural operations are subject to climate variability, declining soil quality, resource scarcity, and unscientific farming methods. Traditional farming practices depend heavily on historic heuristics or intuition, resulting in severe inefficiencies:

- Sub-optimal Yields: Crops are planted in soil chemistries or climates for which they are poorly suited, suppressing yield potential.
- Nutrient Over-application: Inefficient fertilizer use depletes micro-nutrients, builds soil salinity, compacts soil, and causes run-off water pollution.
- Financial Risk: Farmers face high production risks due to weather variability and a lack of data-driven forecasting tools.

2. OptiCrop Core Objective

OptiCrop addresses these vulnerabilities by developing a data-driven production optimization engine. It processes NPK levels, soil pH, temperature, humidity, and rainfall to select optimal crop profiles, predict yield, and provide precise chemical amendment guidelines to balance soil nutrients, improve resource efficiency, and support sustainable farming
